

Preexisting Spatial Biases Influence the Encoding of Information into Visual Working Memory

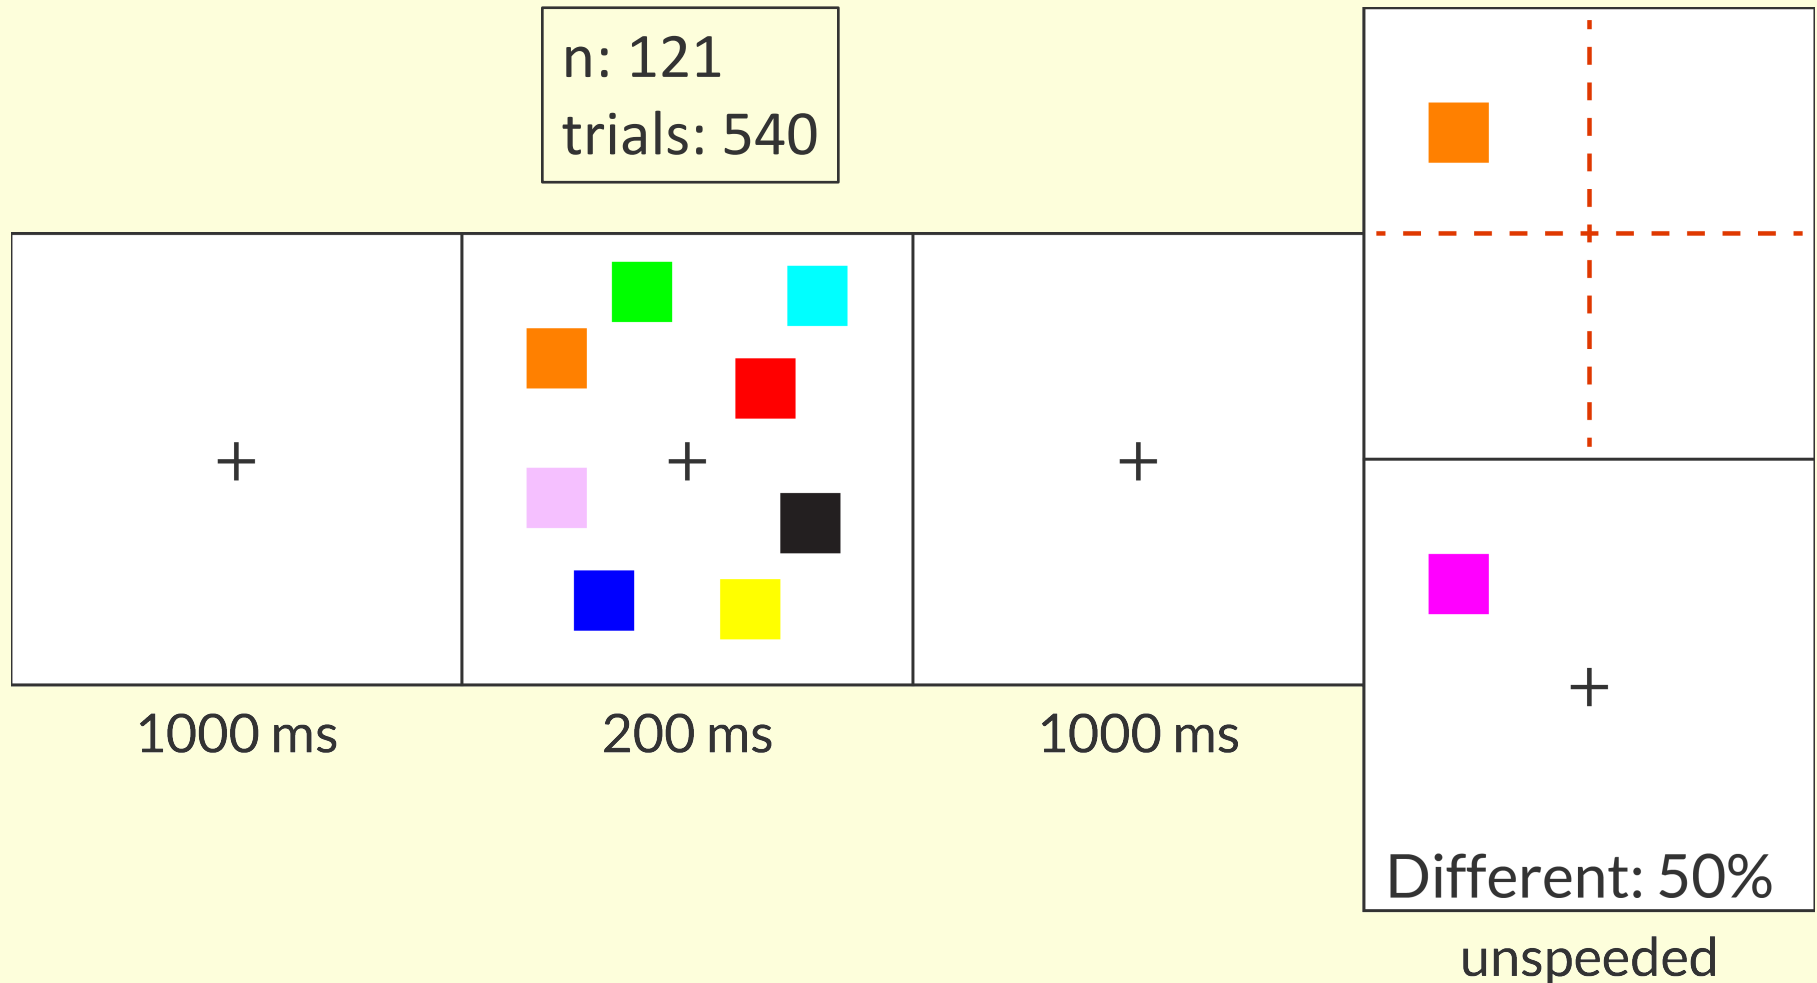

Colin Quirk | Kirsten Adam | Ed Vogel

Introduction

Which items are stored when a display contains more information than you can remember?

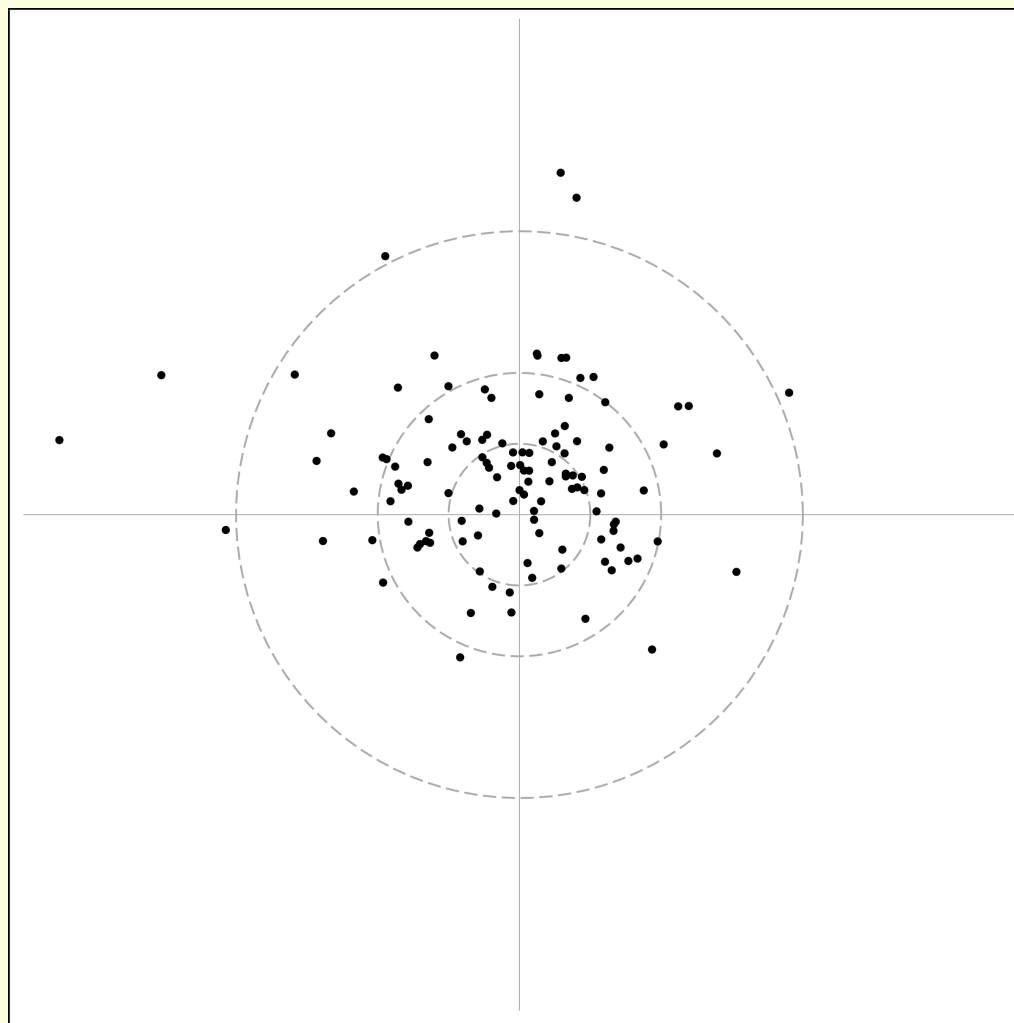

Experiment 1 Procedure

Experiment 1 Results

Top Accuracy - Bottom Accuracy

Right Accuracy - Left Accuracy

Stimulus Properties

Brady and Tenenbaum (2013) found that subjects are consistent in their performance when viewing the exact same change detection displays.

Experiment 2 Results

Random Arrays

n = 121 | trials = 540

All other pairwise comparisons significant at $p < 0.05$

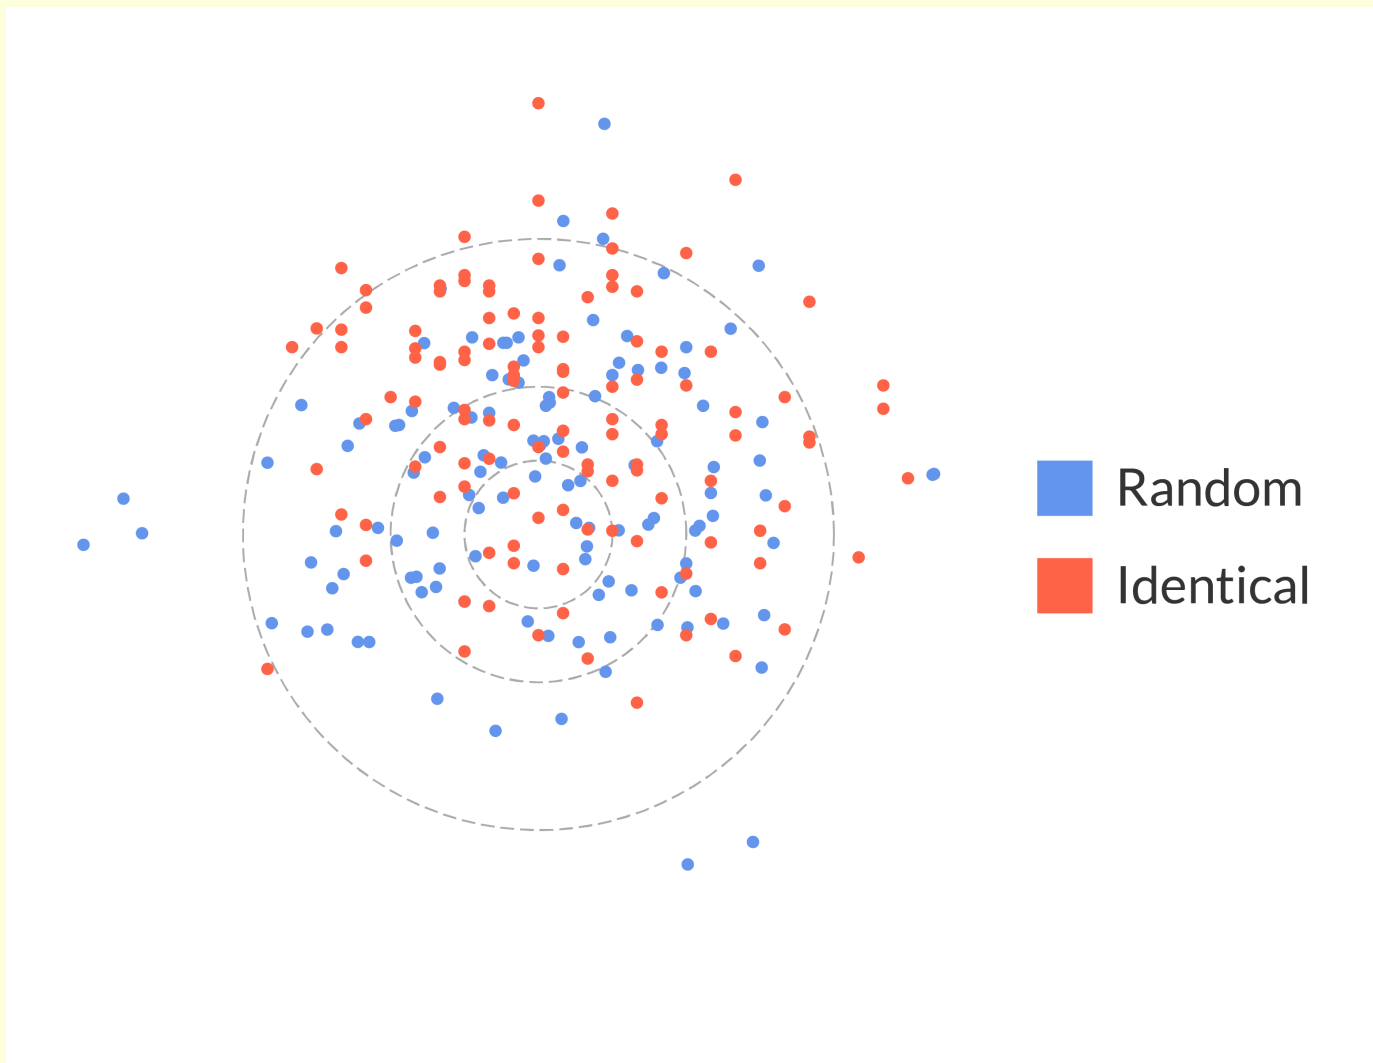

Identical Arrays

n = 279 | trials = 120

All pairwise comparisons significant at $p < 0.05$

Top Accuracy – Bottom Accuracy

Right Accuracy – Left Accuracy

Capacity Differences

Experiment 3 Results

All Quadrants

n = 281 | observations = 720

Forced Hemifield

n = 110 | observations = 720

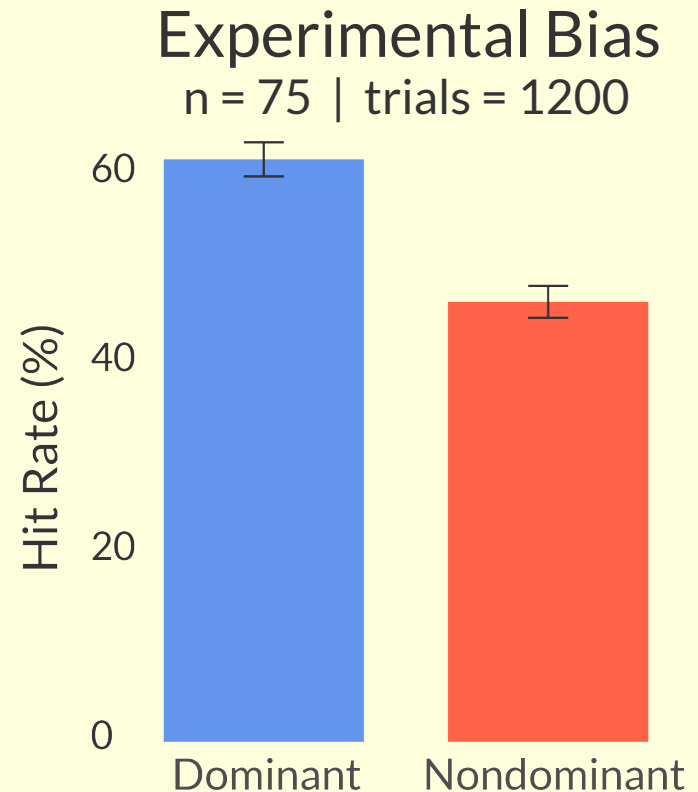

Top Accuracy - Bottom Accuracy

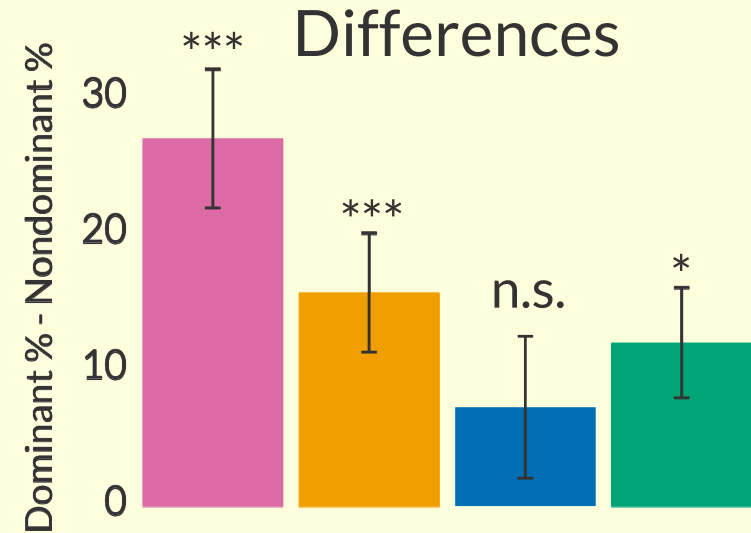

Right Accuracy - Left Accuracy

Selection Bias

Umemoto et al. (2010) found that participants can implicitly learn where changes in a display are more likely to occur

Experiment 4 Results

Conclusion

Over multiple experiments (470340 observations), we have repeatedly observed the same pattern of performance differences across quadrants.

Preliminary results seem to suggest this is due to a bias in selection, as opposed to something about stimulus properties or capacity

Complete working memory models need to account for these existing biases when attempting to estimate capacity
